

Mining High-Utility Spatial Patterns in Utility Databases

What is High-Utility Spatial pattern mining?

High utility pattern mining aims to discover all the patterns with utility of pattern is no less than user-specified **minimum utility** threshold **minutil** and no distance between any two of its items should be no greater than user-specified **maximum distance**.

What is the utility database?

A utility database is a collection of transaction, where each transaction contains a set of items and a positive integer called **internal utility** respectively. And each unique item in database is also associated with another positive number called **external utility** for each transaction.

Transactions	external utilities
(a,2) (b,3) (c,1) (g,1)	5 4 3 2
(b,3) (c,2) (d,3) (e,2)	5 2 9 3
(a,2) (b,1) (c,3) (d,4)	2 3 5 6
(a,3) (c,2) (d,1) (f,2)	1 3 4 6
(a,3) (b,1) (c,2) (d,1) (g,2)	2 5 3 6 1
(c,2) (d,2) (e,3) (f,1)	2 3 4 5
(a,2) (b,1) (c,1) (d,2)	5 4 3 2
(a,1) (e,2) (f,2)	4 8 3
(a,2) (b,2) (c,4) (d,2)	7 4 9 8
(b,3) (c,2) (d,2) (e,2)	5 9 10 24

Note: Duplicate items must not exist in a transaction.

Acceptable format of utility databases in PAMI

Each row in a utility database must contain only items, total sum of utilities and utility values.

```

a b c g:7:2 3 1 1:5 4 3 2
b c d e:10:3 2 3 2:5 2 9 3
a b c d:10:2 1 3 4:2 3 5 6
a c d f:7:3 2 1 2:1 3 4 6
a b c d g:9:3 1 2 1 2:2 5 3 6 1
c d e f:8:2 2 3 1:2 3 4 5
a b c d:6:2 1 1 2:5 4 3 2
a e f:5:1 2 2:4 8 3
a b c d:10:2 2 4 2:7 4 9 8
b c d e:9:3 2 2 2:5 9 10 24

```

Understanding the statistics of database

To understand about the database. The below code will give the detail about the transactional database.

- Total number of transactions (Database size)
- Total number of unique items in database
- Minimum length of transaction that existed in database
- Average length of all transactions that exists in database
- Maximum length of transaction that existed in database
- Minimum utility value exists in database
- Average utility exists in database
- Maximum utility exists in database
- Standard deviation of transaction length
- Variance in transaction length
- Sparsity of database

The sample code

```

import PAMI.extras.dbStats.utilityDatabaseStats as stats

obj = stats.utilityDatabaseStats('sampleInputFile.txt', ' ')
obj.run()
obj.printStats()

```

What is the input to high-utility spatial pattern mining algorithms

Algorithms to mine the high-utility spatial patterns requires utility database, neighbour database, minUtil and separator (specified by user).

- Input utility database is accepted in `path` format
- Neighbour input file is accepted in `path` format
- minUtil should be mentioned in **count**.
- separator (delimiter used in input file) default delimiter is `\t`

What is the output of high-utility spatial pattern mining algorithms

The output of these algorithms is in two ways:

- Saves the patterns in user specified output file.
- Returns the patterns in dataframe variable.

How to run the high-utility spatial pattern algorithm in terminal

- Download the code from github.
- Navigate to PAMI folder where you downloaded the file.
- Go to highUtilitySpatialPattern/basic folder

And execute the following command on terminal.

```
python3 algorithmName.py path of Sample input file path of
neighbour file $minUtil$ separator
```

Sample command to execute the HDSHUIM algorithm in highUtilityPattern/basic folder

```
python3 HDSHUIM.py /Users/Downloads/inputFile.txt
/Users/Downloads/neighbourFile.txt $20$ ' '
```

How to implement the HDSHUIM algorithm by importing PAMI package

Import the PAMI package executing: **pip3 install PAMI**

Run the below sample code by making simple changes

- Replace sampleInputFile name or path in place of iFile and sampleNeighbourFile name or path in place of nFile and sampleOutputFileName in place of oFile.
- Specify the minUtil (like 10) in place of minUtil
- Specify the separator of input file after minUtil. (If no separator is specified the default tab separator is considered for input file)

```
import PAMI.highUtilitySpatialPattern.basic.HDSHUIM as alg
obj = alg.HDSHUIM(iFile, nFile, minUtil, sep)
obj.startMine()
obj.savePatterns(oFile) (to store the patterns in file)
Df = obj.getPatternsAsDataFrame() (to store the patterns in dataframe)
obj.printStats() (to print the no of patterns, runtime and memory consumption details)
```

What is the output of high utility spatial pattern mining algorithms

Returns the pattern and utility respectively with \$minUtil=20\$

The output in file format:

The format followed to save in file is: `pattern : utility`

```
a d : 22
a d c : 34
a c : 27
d c : 35
```

The output in DataFrame format:

	Patterns	Utility
0	a d	22
1	a d c	34
2	a c	27
3	d c	35
